DEPARTMENT OF STATISTICS
STANFORD UNIVERSITY
STANFORD, CALIFORNIA

1. Introduction. Let W(t),  $t \ge 0$ , W(0) = 0 be a standard Wiener process, independent of N(t),  $t \ge 0$ , N(0) = 0, a Poisson process with (constant) unit jumps, and  $EN(t) = \lambda t$ ,  $t \ge 0$ . Let their sigma fields be  $F(t) = \sigma(W(s), 0 \le s \le t)$  and  $G(t) = \sigma(N(s), 0 \le s \le t)$ , respectively. Let X(t) be a stochastic process that (for  $\frac{\partial X}{\partial t} = X_t$ ) satisfies the Ito stochastic differential equation

(1.1) 
$$X_{t}(t) = u(X(t))dt + dW(t) + dN(t)$$
  
 $X(0) = x$ ,

where x is real, and u(X(t)) is measurable with respect to  $\sigma(F(t) \cup G(t))$ (i.e. u is non-anticipative) and satisfies, for A, B constants, B > 0, and |A| < B,

$$(1.2) \quad |u-A| \leq B$$

for all  $0 \le t \le T$ ,  $0 < T \le \infty$  a constant. One cost function for a given u satisfying (1.2) is, for  $\alpha > 0$  a constant, and  $\phi(x)$  a symmetric positive, increasing on the positive x-axis function of polynomial growth as  $x \to \infty$ , that is, for some  $\beta > 0$ ,

(1.3) 
$$\varphi(x)/|x|^{\beta} \to 0$$
 as  $|x| \to \infty$ ,  $\varphi(x) \to \infty$ , and  $\varphi_{xx}(x) \to \infty$  as  $x \to \infty$ .

(1.4) 
$$J(u) = \int_0^T e^{-\alpha s} E(\varphi(x(s)) + |u(X(s))|) ds.$$

Another cost function to be considered is

(1.5) 
$$K(u) = \int_0^T e^{-\alpha s} E(\phi(X(s)) + u^2(X(s))) ds$$
.

This latter cost function will be briefly treated in section 4.

The object is to characterize the optimal u for which J or K is minimized, respectively. The cases  $T < \infty$  and  $T = \infty$  are treated separately. The existence of an optimal u depends on assumptions about the asymptotic behavior of certain partial differential-difference equations. The method employs a suitable Bellman equation, a maximum principle for parabolic partial differential-difference equations and the Ito rule. The method follows [4].

# 2. Finite Interval Control.

Let  $T < \infty$ . Define, for  $0 \le t \le T$ ,

(2.1) 
$$V = V(x,t) = \inf_{|u-A| < B} \int_{0}^{t} e^{-\alpha s} E(\phi(X^{2}(s)) + |u(X(s))|) ds$$

and

$$V(x,0) = x.$$

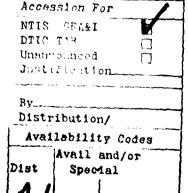

Writing  $\int_{0}^{E} = \int_{0}^{h} + \int_{h}^{h+h} - \int_{e}^{h+h}$ , heuristic arguments (or see

[2], pp. 179-180) yield a Bellman equation (where  $V \equiv V(x,t)$ ,

$$v_x = \frac{\partial v}{\partial x}$$
,  $v_{xx} = \frac{\partial^2 v}{\partial x^2}$ ,  $u = u(x)$ 

(2.2) 
$$\varphi(x) + \inf_{|u-A| < B} (uV_x + |u|) + \frac{1}{2} V_{xx} - \alpha V - V_E$$

 $+ \lambda(V(x+1,t)-V) = 0.$ 

OTIC COPY (NSPECTED) Define

(2.3) 
$$g(a) \equiv \inf_{|u-A| \le B} (ua+|u|) = \begin{cases} (B-A)(1-a) & \text{if } a \ge 1 \\ 0 & \text{if } |a| < 1 \\ (A+B)(1+a) & \text{if } a \le -1 \end{cases}$$

Then (2.2), (2.3) become

(2.4) 
$$g + g(V_x) + \frac{1}{2}V_{xx} - \alpha V - V_t + \lambda(V(x+1,t) - V) = 0.$$

On heuristic grounds, a solution to (2.4) is sought such that for functions  $b_1(t) < b_2(t)$ ;  $0 \le t \le T$  to be determined,

(2.5a) 
$$\varphi + (A+B)(1+V_x) + \frac{1}{2}V_{xx} - \alpha V - V_t$$
  
  $+ \lambda(V(x+1,t) - V) = 0$ 

for 
$$x \leq b_1(t)$$
,

(2.5b) 
$$\varphi + \frac{1}{2} V_{xx} - \alpha V - V_t + \lambda (V(x+1,t) - V) = 0$$
  
for  $b_1(t) < x < b_2(t)$ ,

and

(2.5c) 
$$\varphi + (B-A)(1-V_X) + \frac{1}{2}V_{XX} - \alpha V - V_t + \lambda(V(x+1,t)-V) = 0$$
  
for  $x \ge b_2(t)$ .

The functions  $b_1(t)$ ,  $b_2(t)$  are to be obtained from these matching conditions, where for  $0 \le t \le T$ ,

$$V \equiv V_1$$
 in (2.5a),  $V \equiv V_2$  in (2.5b),  $V \equiv V_3$  in (2.5c):

$$V_1(b_1(t),t) = V_2(b_1(t),t)$$

(2.6) 
$$V_{2}(b_{1}(t),t) = V_{3}(b_{1}(t),t)$$

$$V_{1,x}^{(b_1(t),t)} = V_{2,x}^{(b_1(t),t)} = -1$$

$$V_{2,x}^{(b_2(t),t)} = V_{3,x}^{(b_2(t),t)} = +1.$$

(2.7) 
$$V_1(x,0) = V_2(x,0) = V_3(x,0) = 0.$$

(2.7a) 
$$V_{3,xx}(b_2(t),t) \ge 0$$

(2.7b) 
$$V_{2,xx}(b_1(t),t) \ge 0.$$

For R a constant, denote

(2.3) 
$$J(x,t,R) = \int_0^t e^{-\alpha s} \left[ E(\phi(Rs+W(s)+N(s)+x)+|R|) \right] ds.$$

It may be verified that J(x,t,A+B) is a particular solution to (2.5a), that J(x,t,0) is a particular solution to (2.5b) and that J(x,t,A-B) is a particular solution to (2.5c). The solutions to (2.5a-c) will be shown to follow if this condition holds.

Assumption 1. There is a non-zero solution, for each t,

$$H_1(x,t)$$
 with  $H_1(x,0) = 0$  to  $(H = H(x,t))$ 

(2.9) 
$$(A+B)(1+H_x) + \frac{1}{2}H_{xx} - \alpha H - H_t + \lambda(H(x+1,t) - H) = 0$$

such that

to

(2.10) 
$$H_{1}(x,t) = 0(e^{+rx})$$

$$H_{1,xx}(x,t) = 0(e^{+fx})$$

for some r > 0,  $\ell > 0$ , as  $x \rightarrow -\infty$ .

Also, there is a non-zero solution  $H_2(x,t)$  with  $H_2(x,0) = 0$  to

(2.11) 
$$\frac{1}{2} H_{xx} - \alpha H - H_t + \lambda(H(x+1,t)-H) = 0.$$

Further, there is a non-zero solution  $H_3(x,t)$  with  $H_3(x,0) = 0$ 

(2.12) 
$$(3-A)(1-H_x) + \frac{1}{2}H_{xx} - \alpha H - H_t + \lambda(H(x+1,t)-H) = 0$$

such that

(2.13) 
$$H_3(x,t) = 0(e^{-kx})$$

$$H_{3,xx}(x,t) = 0(e^{-cx})$$

for some k > 0, c > 0, all t, as  $x \rightarrow +\infty$ .

If the above Assumption 1 holds then let

$$(2.14a)$$
  $V_1(x,t) \equiv J(x,t,A+B) + H_1(x,t)$ 

(2.14b) 
$$V_2(x,t) \equiv J(x,t,0) + H_2(x,t)$$

(2.14c) 
$$V_3(x,t) \equiv J(x,t,A-B) + H_3(x,t)$$
.

Assumption 2. The  $V_L(x,t)$ ,  $1 \le l \le 3$  of (2.14a-c) which satisfy (2.5a-c) respectively, and conditions (2.6), (2.7), determine  $b_1(t) < b_2(t)$ . This motivates

Theorem 1. If the conditions of section 2 and Assumptions 1 and 2 hold for  $0 \le t \le T < \infty$ , then the optimal  $u_0$  may be expressed in closed loop form as

(2.15) 
$$u_0(X_0(t)) = \begin{cases} A+B & \text{if } X_0(t) \le b_1(T-t) \\ 0 & \text{if } b_1(T-t) < X_0(t) < b_2(T-t) \\ A-B & \text{if } X_0(t) \ge b_2(T-t) \end{cases}$$

where

(2.16) 
$$dx_0(t) = u_0(X_0(t))dt + dW(t) + dN(t)$$
  
 $X_0(0) = x$ 

<u>Proof.</u> Let  $D = V_{xx}$ , (omitting (x,t) arguments).

Claim.  $D \ge 0$  all (x,t).

Proof of Claim. From (2.4), omitting (x,t), let

(2.17) 
$$L(D) \equiv g(D_x) + \frac{1}{2}D_{xx} - (\alpha + \lambda)D - D_t = -\phi_{xx} - \lambda D(x+1).$$

From (1.3), the conditions on  $\varphi$ , and (2.8) - (2.14), it follows that, for each t,

$$(2.18) \quad D > 0 \text{ as } |x| \rightarrow \infty.$$

Suppose that there is an  $r>b_2$  and a  $\gamma$ ,  $0<\gamma<1$  for fixed t, such that

(2.19) 
$$D(x) < 0$$
  $b_2 < r-y < x < r$ 

$$(2.19a) D(r) = 0$$

(2.20) 
$$D(x) > 0$$
,  $x > r$ .

We now obtain a contradiction to (2.19).

From (1.3),  $\phi_{xx} > 0$ , hence (2.17) and (2.20) imply that

$$L(D) < 0, x \ge r-1.$$

It follows from a maximum principle (Lemma 1(after multiplying by -1)[1], p. 34) that D cannot have a negative minimum for the fixed t, for  $x \ge r-\gamma$ . From this and (2.7a), (2.18),(2.20), if follows that if D were negative for any  $x \ge r-\gamma$ , it would have a negative minimum, which is not allowed by the maximum principle. Hence  $D \ge 0$  for  $x \ge r-\gamma$ , contradicting (2.19) and completing the claim for  $x \ge b_2$ . For  $x < b_2$ , a similar argument using (2.7b), (2.18) yields that D(x) > 0 for  $b_2-\delta < x < b_2$  for appropriate  $0 < \delta < 1$ . Continuing the argument by iteration yields that  $D(x) \ge 0$  all x, for each t.

The claim implies that  $V_{x}$  is increasing in x for each t and hence that (2.5)-(2.14) indeed yields a solution to the Bellman equation (2.4).

To show  $u_0$  is optimal, define, for  $0 \le t \le T$ 

$$(2.21) \quad K(X(t),t) \equiv V(X(t),T-t)e^{-\alpha t}.$$

Noting that K(X(0),0) = V(x,T) and K(X(T),T) = 0, the Ito rule ([2],pp.125-126) applied to (2.21) for an admissible u and its corresponding X(t) yields, upon integrating from 0 to T, and adding and subtracting appropriate terms, that

$$(2.22) \int_{0}^{T} e^{-\alpha s} (\varphi(X(s)) + |u(X(s))|) ds - V(x,T) =$$

$$\int_{0}^{T} e^{-\alpha s} (\varphi(X(s)) + g(V_{X}(X(s),T-s)) + \frac{1}{2} V_{XX}(X(s),T-s)$$

$$-\alpha V(X(s),T-s) - V_{t}(X(s),T-s)) ds$$

$$+ \int_{0}^{T} e^{-\alpha s} V(X(s),T-s) dN(s)$$

$$+ \int_{0}^{T} e^{-\alpha s} V_{X}(X(s),T-s) dW(s)$$

$$+ \int_{0}^{T} e^{-\alpha s} V_{X}(X(s),T-s) dW(s)$$

The fourth integral on the right side of (2.22) is non-negative. Upon taking expectations in (2.22), the third integral on the right becomes zero.

On combining the first and second integrals on the right after taking expectations, and suppressing the X(s) and the (X(s),T-s) arguments, one obtains from (2.22),

(2.23) 
$$\int_{0}^{T} e^{-\alpha s} \mathbb{E}(\varphi + |u|) ds - V(x,T) =$$

$$\int_{0}^{T} e^{-\alpha s} \mathbb{E}(\varphi + g(V_{x}) + \frac{1}{2} V_{xx} - \alpha V - V_{t} + \lambda(V(X(s) + 1, T - s) - V)) ds$$

$$\int_{0}^{T} e^{-\alpha s} \mathbb{E}(uV_{x} + |u| - g(V_{x})) ds.$$

The first integral on the right of (2.23) is zero by (2.4) and the second integral on the right is non-negative by definition of g in (2.3), with equality if  $u=u_0$ . Hence from (2.23),

(2.24) 
$$\int_0^T e^{-\alpha s} \mathbb{E}(\varphi + |u| ds \ge V(x,T)$$

with equality if  $\mathbf{u} = \mathbf{u}_0$ , showing that  $\mathbf{u}_0$  is optimal. This completes Theorem 1.

3. Infinite Interval Control. Assume that the conditions of section 2 hold and let  $T = \infty$ . The cost function is then

(3.1) 
$$J(u) = \int_0^\infty e^{-\alpha s} \mathbb{E}(\varphi(X(s)) + |u(X(s))|) ds$$

which is finite by (1.3) for admissible u.

Define  $V \equiv V(x)$  as

(3.2) 
$$V(x) = \inf_{|u-A| \le B} \int_{0}^{\infty} e^{-\alpha s} E(\varphi(X(s)) + |u(X(s))|) ds$$

where X(0) = x, a constant.

By writing  $\int_0^\infty = \int_0^h + \int_0^\infty$ , heuristic arguments (see[2], pp. 179-180), yield a Bellman equation, using the abbreviated arguments in (2.2),

(3.3) 
$$\varphi(x) + \inf_{|u-A| \le B} (uV_x + |u|) + \frac{1}{2}V_{xx} - \alpha V + \lambda(V(x+1) - V) = 0.$$

As in (2.3), (2.4),

(3.4) 
$$\varphi(x) + g(V_x) + \frac{1}{2}V_{xx} - \alpha V + \lambda(V(x+1)-V) = 0$$

On heuristic grounds, a solution to (3.4) is sought such that for numbers  $b_1 < b_2$  to be determined below, omitting x arguments,

(3.5a) 
$$\varphi + (A+B)(1+V_X) + \frac{1}{2}V_{XX} - \alpha V + \lambda(V(x+1)-V) = 0$$
  
for  $x \le b_1$ 

(3.5b) 
$$\varphi + \frac{1}{2} V_{xx} - \alpha V + \lambda (V(x+1) - V) = 0$$
  
for  $b_1 < x < b_2$ ,

(3.5c) 
$$\varphi + (B-A)(1-V_x) + \frac{1}{2}V_{xx} - \alpha V + \lambda(V(x+1)-V) = 0$$
  
for  $x \ge b_2$ .

The  $b_1 < b_2$  are to be determined from the following matching conditions, where  $V \equiv V_1$  in (3.5a),  $V \equiv V_2$  in (3.5b) and  $V \equiv V_3$  in (3.5c).

$$v_{1}(b_{1}) = v_{2}(b_{1})$$

$$v_{2}(b_{2}) = v_{3}(b_{2})$$

$$v_{1,x}(b_{1}) = v_{2,x}(b_{1}) = -1$$

$$V_{2,x}(b_2) = V_{3,x}(b_2) = +1.$$

(3.6a) 
$$V_{3,xx}(b_2) \ge 0$$
  $V_{2,xx}(b_1) \ge 0$ .

For R a constant, denote

(3.7) 
$$J(x,R) = \int_0^\infty e^{-\alpha s} E(\varphi(Rs+W(s)+N(s)+x)+|R|)ds.$$

It may be verified that J(x,A+B) is a particular solution to (3.5a), that J(x,2) is a particular solution to (3.5b) and J(x,A-B) is a

particular solution to (3.5c).

Assumption 3. There is a non-zero solution  $H_1(x)$  to (omitting x argument)

(3.8) 
$$(A+B)(1+H_X) + \frac{1}{2}H_{XX} - \alpha H + \lambda(H(x+1)-H) = 0$$

such that

(3.9) 
$$H_{1}(x) = O(e^{+ux})$$

$$H_{1,xx}(x) = O(e^{+vx})$$

for some u > 0, v > 0, as  $x \rightarrow -\infty$ .

There is a non-zero solution  $H_2(x)$  to

(3.10) 
$$\frac{1}{2} H_{xx} - \alpha H + \lambda (H(x+1)-H) = 0.$$

There is a non-zero solution  $H_3(x)$  to

(3.11) 
$$(B-A)(1-H_X) + \frac{1}{2}H_{XX} - \alpha H + \lambda(H(x+1)-H) = 0$$

such that

(3.12) 
$$H_3(x) = 0(e^{-qx})$$

$$H_{3,xx}(x) = 0(e^{-px})$$

for some p > 0, q > 0 as  $x \rightarrow +\infty$ .

Now one sets

$$(3.13a)$$
  $V_1(x) = J(x,A+B) + H_1(x)$ 

(3.135) 
$$V_2(x) = J(x,0) + H_2(x)$$

(3.13c) 
$$V_3(x) = J(x,A-B) + H_3(x)$$
.

.

Assumption 4.

(3.14) The  $b_1 < b_2$  are determined by the  $V_{\ell}(x)$ ,  $1 \le \ell \le 3$  of (3.13 a-c).

Theorem 2. Under the assumptions of this section, the optimal  $u = u_1$  may be expressed as

(3.15) 
$$u_1(X_1(t)) = \begin{cases} A+B & \text{if } X_1(t) \leq b_1 \\ 0 & \text{if } b_1 < X_1(t) < b_2 \\ A-B & \text{if } X_1(t) \geq b_2 \end{cases}$$

where

(3.16) 
$$dX_1(t) = u_1(X_1(t))dt + dW(t) + dN(t)$$
  
 $X_1(0) = x$ 

<u>Proof.</u> Let  $D = V_{xx}$ , suppressing the x-arguments.

Claim.  $D \ge 0$  all x.

Proof of Claim. From (3.4)

(3.17) 
$$K(D) \equiv g(D_x) + \frac{1}{2}D_{xx} - (\alpha + \lambda)D = -\phi_{xx} - \lambda D(x+1).$$

By an argument identical to that given in the pooof of Theorem 1, using the appropriate maximum principle ([1], Theorem 18, p. 53), it follows that  $D(x) \ge 0$  for all x.

The claim implies that  $V_{\rm X}$  is increasing in x and hence that (3.5)-(3.14) yields a solution to (3.4).

To show  $u_1$  is optimal, define, for  $t \ge 0$ ,

(3.18) 
$$R(X(t)) \equiv V(X(t))e^{-\alpha t}.$$

Noting that R(0) = V(x), the Ito rule ([2], pp. 125-126) applied to R(X(t)) followed by integration and adding and subtracting appropriate terms yields (arguments on the right side not indicated are X(s))

(3.19) 
$$\int_{0}^{E} e^{-\alpha s} (\varphi(X(s)) + |u(X(s))|) ds + V(X(t)) e^{-\alpha t} - V(x) =$$

$$\int_{0}^{E} e^{-\alpha s} (\varphi + g(V_{x}) + \frac{1}{2} V_{xx} - \alpha V) ds + \int_{0}^{E} e^{-\alpha s} V dN(s)$$

$$+ \int_{0}^{E} e^{-\alpha s} V_{x} dW(s) + \int_{0}^{E} e^{-\alpha s} (\varphi + |u| - g(V_{x})) ds.$$

The fourth integral on the right is non-negative by the definition of g(x). Upon taking expectations in (3.19), the third integral on the right vanishes, and the first and second terms on the right may be combined to obtain (again the arguments not indicated are X(s))

(3.20) 
$$\int_{0}^{t} e^{-\alpha s} E(\varphi + |u|) ds + e^{-\alpha t} EV(X(t)) - V(x) =$$

$$\int_{0}^{t} e^{-\alpha s} E(\varphi + g(V_{x}) + \frac{1}{2} V_{xx} - \alpha V + \lambda(V(X(s) + 1) - V)) ds$$

$$+ \int_{0}^{t} e^{-\alpha s} E(uV_{x} + |u| - g(V_{x})) ds.$$

By (3.4), the first integral on the right of (3.20) is zero, and the second integral on the right is non-negative by the definition of g. From (1.3), (3.5)-(3.14), and the bounds on |u|, it follows that there is a constant L > 0 such that for all t,

(3.21) 
$$E(V(X(t)))e^{-\alpha t} \leq Le^{-\alpha t}$$

letting  $t \rightarrow \infty$  in (3.20), and using (3.21) one obtains

(3.22) 
$$\int_0^{\infty} e^{-\alpha s} E(\varphi + |u|) ds \ge V(x)$$

and (3.23) 
$$\int_{0}^{\infty} e^{-\alpha s} E(\varphi(X_{1}(s)) + |u_{1}(X_{1}(s))|) ds = V(x)$$

so that (3.22), (3.23) yield that  $u_1$  is optimal, completing Theorem 2.

4. Alternate Cost Function. The same models as in sections 1-3 with certain other cost functions may be treated in a similar way. For example, the cost function (1.5) yields, for  $T < \infty$ , a Bellman equation (the (x,t) arguments are omitted)

(4.1) 
$$\varphi + h(V_x) + \frac{1}{2} V_{xx} - \alpha V - V_t + \lambda(V(x+1,t) - V) = 0$$

where

$$(4.2) h(a) = \inf_{|\mathbf{u}-\mathbf{A}| \le B} (\mathbf{u}\mathbf{a}+\mathbf{u}^2) = \begin{cases} (A+B)(\mathbf{a}+A+B) & \text{if } -\frac{\mathbf{a}}{2} \ge A+B \\ -\frac{\mathbf{a}^2}{4} & \text{if } A-B < -\frac{\mathbf{a}}{2} < A+B \\ (A-B)(\mathbf{a}+A-B) & \text{if } -\frac{\mathbf{a}}{2} \le A-B \end{cases}$$

and from (4.2),

(4.3) 
$$u = A-B$$
 if  $-\frac{a}{2} < A-B$ ;  $u = -\frac{a}{2}$  if  $A-B < -\frac{a}{2} < A+B$ ;  $u = A+B$  if  $-\frac{a}{2} > A+B$ .

One seeks a solution to (4.1) of the form

$$(4.4a) \quad \varphi + (A+B) (V_x + A+B) + \frac{1}{2} V_{xx} - \alpha V - V_t + \lambda (V(x+1;t) - V) = 0$$
if  $x \le k_1(t)$ 

$$(4.4b) \quad \varphi - \frac{1}{4}(V_x)^2 + \frac{1}{2} V_{xx} - \alpha V - V_t + \lambda (V(x+1,t) - V) = 0$$
if  $k_1(t) < x < k_2(t)$ 

and

(4.4c) 
$$\varphi + (A-B)(V_x + A-B) + \frac{1}{2}V_{xx} - \alpha V - V_t + \lambda(V(x+1,t) - V) = 0$$
  
if  $x \ge k_2(t)$ .

The  $k_1(t)$ ,  $k_2(t)$  are to be determined by, for  $V \equiv V_1$  in (4.4a),  $V \equiv V_2$  in (4.4b),  $V \equiv V_3$  in (4.4c), for  $0 \le t \le T$ ,

$$V_{1}(k_{1}(t),t) = V_{2}(k_{1}(t),t)$$

$$V_{2}(k_{2}(t),t) = V_{3}(k_{2}(t),t)$$

$$V_{1,x}(k_{1}(t),t) = V_{2,x}(k_{1}(t),t) = -2(A+B)$$

$$V_{2,x}(k_{2}(t),t) = V_{3,x}(k_{2}(t),t) = -2(A-B).$$

and

(4.6) 
$$V_1(x,0) = V_2(x,0) = V_3(x,0) = 0$$
 all x.  
(4.6a)  $V_{2,xx}(k_1(t),t) \ge 0$   
 $V_{3,xx}(k_2(t),t) \ge 0$ .

The maximum principle ([1], Lemma 1 p. 34) may be applied to (4.4a), (4.4c) as in Theorem 1, as these are linear in the  $V_{\rm x}$  term. Similarly, for R a constant, if one defines

(4.7) 
$$L(x,t,R) = \int_0^t e^{-\alpha s} E(\phi(Rs+W(s)+N(s)+x)+R^2) ds$$
,

then L(x,A+B) is a particular solution to (4.4a) and L(x,A-B) is a particular solution to (4.4c). Adding an assumption similar to

assumptions 1 and 2 in section 2, and on the boundedness of solutions to (4.4b), one may obtain the optimal  $u_3$  for this problem implicitly in the form

Two (4.8) 
$$u_3(X_3(t),t) = \begin{cases} A+B & \text{if } X_3(t) \le k_1(T-t) \\ -\frac{1}{2}V_x(X_3(t),t) & \text{if } k_1(T-t) < X_3(t) < k_2(T-t) \\ A-B & \text{if } X_3(t) \ge k_2(T-t), \end{cases}$$

where

$$dX_3(t) = u_3(X_3(t))dt + dN(t) + dW(t),$$

using arguments as in Theorem 1.

The case  $T = \infty$  parallels that of section 3. The Bellman equation is, for  $V \equiv V(x)$ ,

(4.9) 
$$\varphi + h(\nabla_x) + \frac{1}{2} \nabla_{xx} - \alpha V + \lambda (V(x+1) - V) = 0$$

and a solution to (4.9) is sought of the form

(4.10a) 
$$\varphi + (A+B) (V_X + A+B) + \frac{1}{2} V_{XX} - \alpha V + \lambda (V(x+1) - V) = 0$$
  
for  $x \le l_1$   
(4.10b)  $\varphi - \frac{1}{4} (V_X^2) + \frac{1}{2} V_{XX} - \alpha V + \lambda (V(x+1) - V) = 0$   
for  $l_1 < x < l_2$ ,

and

(4.10c) 
$$\varphi + (A-B)(V_X + A-B) + \frac{1}{2}V_{XX} - \alpha V + \lambda(V(X+1)-V) = 0$$
for  $x \ge L_2$ 

where the constants  $L_1 < L_2$  are to be determined from the matching conditions where  $V \equiv V_1$  in (4.10a),  $V \equiv V_2$  in (4.10b),  $V \equiv V_3$  in (4.10c)

$$V_{1}(L_{1}) = V_{2}(L_{1})$$

$$V_{2}(L_{2}) = V_{3}(L_{2})$$

$$V_{1,x}(L_{1}) = V_{2,x}(L_{1}) = -2(A+B)$$

$$V_{2,x}(L_{2}) = V_{3,x}(L_{2}) = -2(A-B).$$

$$(4.11a) \qquad V_{2,xx}(L_{1}) \ge 0$$

$$V_{3,xx}(L_{2}) \ge 0.$$
If
$$(4.12) \quad L(x,R) \equiv \int_{0}^{\infty} e^{-\alpha s} (E(\varphi(Rs+W(s)+N(s)+x)+R^{2}) ds,$$

it may be shown that L(x,A+B) is a particular solution to (4.10a) and L(x,A-B) is a particular solution to (4.10c). Adding an appropriate assumption similar to that in section 3, and on the boundedness of solutions to (4.10b), the optimal  $u_4$  is implicitly expressed as

$$(4.13) \quad u_{4}(X_{4}(t)) = \begin{cases} A+B & \text{if } X_{4}(t) \leq \ell_{1} \\ -\frac{1}{2}V_{x}(X_{4}(t)) & \text{if } \ell_{1} < X_{4}(t) < \ell_{2} \end{cases}$$

$$A-B & \text{if } X_{4}(t) \geq \ell_{2}$$

where

$$dX_4(t) = u_4(X_4(t))dt + dW(t) + dN(t)$$

$$X_4(0) = x.$$

## 5. Additional Constraints.

Certain additional constraints may be incorporated and treated by those methods. For example, in the case  $T < \infty$  of section 2, the added constraint

(5.1) 
$$E(\phi(X(a)) + |u(X(a))|) = C$$
,

where a is a constant,  $0 < a \le T$  and C > 0, may be incorporated by adding the condition

$$V_t(x,t)$$
 =  $e^{-\alpha a}C$ 

to the conditions (2.6),(2.7), and proceeding as before. See [3] for another approach.

### 6. Extensions.

The method applies to a variant of the stochastic differential equation (1.1). Let, for  $\beta \neq 0$  a constant,

(6.1) 
$$X_t(t) = (\beta X(t) + u(X(t)) dt + dW(t) + dN(t),$$
  
 $X(0) = x,$ 

with control u(X(t)) satisfying (1.2) as before. Similarly, the cost function J(u) is as in (1.4).

The appropriate Bellman equation for  $T < \infty$  is, where g is as in (2.3),

(6.2) 
$$0 = \varphi(x) + xV_x + g(V_x) + \frac{1}{2}V_{xx} - V_t + \lambda(V(x+1) - V) - \alpha V.$$

A solution of the form (2.5)-(2.7) is sought as before. To obtain a particular solution to, e.g., the Bellman equation

(6.3) 
$$0 = \varphi(x) + xV_{x} + (\triangle + B)(1 + V_{t}) + \frac{1}{2}V_{xx} - \alpha V - V_{t}$$
$$+ \lambda (V(x+1,t) - V) = 0,$$

denote

(6.4) 
$$Y(t) = e^{-\beta t}X(t)$$
.

Then

(6.5) 
$$dY(t) = e^{-\beta t} (A+B) dt + e^{-\beta t} dW(t) + e^{-\beta t} dW(t)$$

Hence, integrating (6.5)

(6.6) 
$$Y(t) = x + \int_{0}^{t} e^{-\beta s} dW(s)$$
  
  $+ \int_{0}^{t} e^{-\beta s} dN(s) + (A+B) \int_{0}^{t} e^{-\beta s} ds$ 

or

(6.7) 
$$X(t) = xe^{\beta t} + \frac{(A+B)}{\beta} (e^{\beta t} - 1) + \int_{0}^{t} e^{\beta (t-s)} dN(s) + \int_{0}^{t} e^{\beta (t-s)} dN(s).$$

It may now be verified that

(6.8) 
$$J(x,t,A+B) \equiv E \int_{0}^{E} (\varphi(xe^{\beta t} + \frac{(A+B)}{\beta}(e^{\beta t} - 1) + \int_{0}^{E} e^{\beta(t-s)} dW(s)) + \int_{0}^{E} e^{\beta(t-s)} dN(s) + (A+B)) ds$$

is a particular solution to (6.3). The rest of the construction and matching and initial conditions and proofs are as in section 2.

20.	. ABSTRACT (Continue on reverse side if nacessary and			
A one-dimensional Wiener plus independent Poisson control process has integrated, discounted non-quadratic cost function with asymmetric bounds on the non-anticipative control, assumed to be a function of the current state. A Bellman equation and maximum principle for partial differential-difference equations may be used to obtain the optimal closed loop control if some assump-				
tions on the asymptotic behavior of certain partial differential-difference equations are met. The finite and infinite integral cases are treated separately.
